## 1. Introduction

The participation in proficiency testing schemes is an essential element of the quality-management-system of every laboratory testing food and feed, cosmetics and food contact materials. The implementation of proficiency tests enables the participating laboratories to prove their own analytical competence under realistic conditions. At the same time they receive valuable data regarding the verification and/or validation of the particular testing method [1, 5].

The purpose of DLA is to offer proficiency tests for selected parameters in concentrations with practical relevance.

Realisation and evaluation of the present proficiency test follows the technical requirements of DIN EN ISO/IEC 17043 (2010) and DIN ISO 13528:2009 / ISO 13528:2015 [2, 3].

## 2. Realisation

### 2.1 Test material

The test material is an common in commerce animal food supplement green lipped mussel powder (*Perna canaliculus*) with an addition of fish powder (coalfish / saithe, *Pollachius virens*). The raw materials were sieved and homogenized. The composition is given in Table 1 below.

Afterwards the samples were portioned to approximately 8 g into metallised PET film bags and chronologically numbered.

Table 1: Composition of DLA-Samples

Ingredients	Content
Green Lipped Mussel Powder Ingredients: Green lipped mussel ( <i>Perna Canaliculus</i> ) Nutrients per 100 g: Protein 53 g	57,6 g/100g
Fish-Powder Ingredients: Coalfish ( <i>Pollachius virens</i> ), coo- ked, dried, ground Nutrients per 100 g: Protein 87 g, salt 2,5 g, fat 5,0 g, carbohydrates 0 g	42,4 g/100g

### 2.1.1 Homogeneity

The **homogeneity of bottled numbered DLA-samples** was checked by 5fold determination of copper by ICP-OES (VDLUFA III, 10.8.2). The repeatability standard deviation of 6,12 % is in the range of the repeatability standard deviation of comparable methods (e.g. the German official method ASU §64 L 00.00-144, s. 3.6.2). The results of the homogeneity test are given in the documentation.

The calculation of the **repeatability standard deviation S<sub>r</sub> of the participants** was also used as an indicator of homogeneity. For 12 of 17 elements it is < 5,0% and for all elements < 10%. Therefore these repeatability standard deviations are similar to precision data of the referring standardized methods (e.g. ASU §64 L 00.00-144, s. 3.6.2) (see Tab. 3) [16-26]. The repeatability standard deviations of the participants' results are given in the tables of statistic data (see 4.1 to 4.20).

Furthermore, the homogeneity was characterized by the **trend line function of participants' results for chronological bottled single samples**. The maximum deviations from the mean value of the trend lines for Al and Pb were below 30% of the target standard deviations  $\sigma_{opt}'$  and  $\sigma_{opt}$ , respectively (s. 5.2 homogeneity) and can therefore be regarded as low.

If the criteria for sufficient homogeneity of the test material are not fulfilled on a particular parameter, the impact on the target standard deviation is checked and optionally the evaluation of the results of the participants will be done using the z'-score considering the standard uncertainty of the assigned value (see 3.8 and 3.11) [3].

### 2.2 Sample shipment and information to the test

Two portions of test material were sent to every participating laboratory in the 17<sup>th</sup> week of 2016. The testing method was optional. The tests should be finished at 9<sup>th</sup> June 2016 the latest.

With the cover letter along with the sample shipment the following information was given to participants:

*The two portions contain identical samples of a food supplement with green-lipped mussel powder and fish powder.*

*In general we recommend to homogenize a representative sample amount before analysis according to good laboratory practice, especially in case of low sample weights.*

**Note:** Please indicate the applied hydrolization method and especially the hydrolization solutions, to ensure better comparability of results. It is also possible to submit several results for one element obtained by different hydrolization methods.

### 2.3 Submission of results

The participants submitted their results in standard forms, which have been handed out with the samples (by email).

The finally calculated concentrations of the parameter as average of duplicate determinations of both numbered samples were used for the statistical evaluation. For the calculation of the repeatability- and reproducibility standard deviation the single values of the double determination were used.

Queried and documented were single results, recovery and the used testing methods.

In case participants submitted several results for the same parameter obtained by different methods these results were evaluated with the same evaluation number with a letter as a suffix and indication of the related method.

From the 15 participants one participant submitted the results delayed in consultation with DLA. All other participants submitted the result in time.

### 3. Evaluation

#### 3.1 Consensus value from participants (assigned value)

The robust mean of the submitted results was used as assigned value ( $X_{pt}$ ) ("consensus value from participants") providing a normal distribution. The calculation was done according to algorithm A as described in annex C of ISO 13528 [3].

The condition is that the majority of the participants' results show a normal distribution or are distributed unimodal and symmetrically. To this end, an examination of the distribution is carried out, *inter alia*, using the kernel density estimate [3, 12].

In case there are indications for sources of higher variability such as a bimodal distribution of results, a cause analysis is performed.

Frequently different analytical methods may cause an anomaly in results' distribution. If this is the case, separate evaluations with own assigned values ( $X_{pti}$ ) are made whenever possible.

The statistical evaluation is carried out for all the parameters for a minimum of 7 values are present.

The actual measurement results will be drafted. Individual results, which are outside the specified measurement range of the participating laboratory (for example with the result  $> 25 \text{ mg/kg}$  or  $< 2,5 \text{ mg/kg}$ ) or the indicating "0" will not be considered for the statistic evaluation [3].

#### 3.2 Robust standard deviation

For comparison to the target standard deviation  $\sigma_{pt}$  (standard deviation for proficiency assessment) a robust standard deviation ( $S^*$ ) was calculated. The calculation was done according to algorithm A as described in annex C of ISO 13528 [3].

#### 3.3 Repeatability standard deviation

The repeatability standard deviation  $S_r$  is based on the laboratory's standard deviation of (outlier free) individual participant results, each under repeatability conditions, that means analyses was performed on the same sample by the same operator using the same equipment in the same laboratory within a short time. It characterizes the mean deviation of the results within the laboratories [3] and is used by DLA as an indication of the homogeneity of the sample material.

In case single results from participants are available the calculation of the repeatability standard deviation  $S_r$ , also known as standard deviation within laboratories  $S_w$ , is performed by: [3, 4].

The relative repeatability standard deviation as a percentage of the mean value is indicated as coefficient of variation  $CV_r$  in the table of statistical characteristics in the results section in case single results from participants are available.

### 3.4 Reproducibility standard deviation

The reproducibility standard deviation  $S_R$  represents a inter-laboratory estimate of the standard deviation for the determination of each parameter on the bases of (outlier free) individual participant results. It takes into account both the repeatability standard deviation  $S_r$  and the within-laboratory standard deviation  $S_s$ . Reproducibility standard deviations of PT's may differ from reproducibility standard deviations of ring trials, because the participating laboratories of a PT generally use different internal conditions and methods for determining the measured values.

In the present evaluation, the specification of the reproducibility standard deviation, therefore, does not refer to a specific method, but characterizes approximately the comparability of results between the laboratories, assumed the effect of homogeneity and stability of the sample are negligible.

In case single results from participants are available the calculation of the reproducibility standard deviation  $S_R$  is performed by: [3, 4].

The relative reproducibility standard deviation as a percentage of the mean value is indicated as coefficient of variation  $CV_R$  in the table of statistical characteristics in the results section in case single results from participants are available. Its meaning is explained in more detail in 3.9.

### 3.5 Exclusion of results and outliers

Before statistical evaluation obvious blunders, such as those with incorrect units, decimal point errors, and results for a another proficiency test item can be removed from the data set [2]. All results should be given at least with 2 significant digits. Specifying 3 significant digits is usually sufficient.

Results obtained by different analytical methods causing an increased variability and/or a bi- or multimodal distribution of results, are treated separately or could be excluded in case of too few numbers of results. For this results are checked by kernel density estimation [3, 12].

Results are identified as outliers by the use of robust statistics. If a value deviates from the robust mean by more than 3 times the robust standard deviation, it is classified as an outlier [3]. Detected outliers are stated for information only, when z-score are  $< -2$  or  $> 2$ . Due to the use of robust statistics outliers are not excluded, provided that no other reasons are present [3].

### 3.6 Target standard deviation (for proficiency assessment)

The target standard deviation of the assigned value  $\sigma_{pt}$  (= standard deviation for proficiency assessment) can be determined according to the following methods.

If an acceptable quotient  $S^*/\sigma_{pt}$  is present, the target standard deviation of the general model by Horwitz is preferably used for the proficiency assessment. It is usually suitable for evaluation of interlaboratory studies, where different analytical methods are applied by the participants. On the other hand the target standard deviation from the evaluation of precision data of an precision experiment is derived from collaborative studies with specified analytical methods.

In cases where both above-mentioned models are not suitable, the target standard deviation is determined based on values by perception, see under 3.6.3.

For information the z-scores of both models are given in the evaluation, if available.

***In the present PT for valuation of all elements the target standard deviation according to the general model of Horwitz was applied (see 3.4.1).***

***Additionally for Al, Ba and I the standard uncertainty was considered by valuating with z'-scores (see 3.6).***

#### 3.6.1 General model (Horwitz)

Based on statistical characteristics obtained in numerous PTs for different parameters and methods Horwitz has derived a general model for estimating the reproducibility standard deviation  $\sigma_R$  [6]. Later the model was modified by Thompson for certain concentration ranges [10]. The reproducibility standard deviation  $\sigma_R$  can be applied as the relative target standard deviation  $\sigma_{pt}$  in % of the assigned values and calculated according to the following equations [3]. For this the assigned value  $X_{pt}$  is used for the concentration  $c$ .

Equations	Range of concentrations	corresponds to
$\sigma_R = 0,22c$	$c < 1,2 \times 10^{-7}$	< 120 µg/kg
$\sigma_R = 0,02c^{0,8495}$	$1,2 \times 10^{-7} \leq c \leq 0,138$	≥ 120 µg/kg
$\sigma_R = 0,01c^{0,5}$	$c > 0,138$	> 13,8 g/100g

with  $c$  = mass content of analyte (as relative size, e.g. 1 mg/kg = 1 ppm =  $10^{-6}$  kg/kg)

### 3.6.2 Value by precision experiment

Using the reproducibility standard deviation  $\sigma_R$  and the repeatability standard deviation  $\sigma_r$  of a precision experiment (collaborative trial or proficiency test) the target standard deviation  $\sigma_{pt}$  can be derived considering the number of replicate measurements  $m$  of participants in the present PT [3]:

$$\sigma_{pt} = \sqrt{\sigma_R^2 - \sigma_r^2 \left( \frac{m-1}{m} \right)}$$

The values given in Table 2 relative repeatability standard deviation ( $RSD_r$ ) and relative reproducibility standard deviation ( $RSD_R$ ) were determined in collaborative trials using the specified methods.

The in the table indicated resulting target standard deviations  $\sigma_{pt}$  were used for evaluation of the results.

For information the target standard deviations according to Horwitz are given additionally.

### 3.6.3 Value by perception

The target standard deviation for proficiency assessment can be set at a value that corresponds to the level of performance that the coordinator would wish laboratories to be able to achieve [3].

For the present evaluation the target standard deviation according to 3.6.1 was regarded suitable partly using the z'-scores.

**Table 2:** Relative repeatability standard deviations ( $RSD_r$ ) and relative reproducibility standard deviations ( $RSD_R$ ) from precision experiments and resulting target standard deviations  $\sigma_{opt}$  [16-26]

Para-meter	Matrix	Mean values	RSD <sub>r</sub>	RSD <sub>R</sub>	$\sigma_{opt}$	Method / Literature
Al	cocoa powder	205	3,25%	5,83%	5,36%	ICP-MS [16]

	infant food soya	43,5	2,60%	6,89%	6,64%	ICP-OES (22)

<sup>1</sup> used in evaluation (s. chapter 4)

### 3.7 z-Score

To assess the results of the participants the z-score is used. It indicates about which multiple of the target standard deviation ( $\sigma_{pt}$ ) the result ( $x_i$ ) of the participant is deviating from the assigned value ( $X_{pt}$ ) [3].

Participants' z-scores are derived from:

$$z_i = \frac{(x_i - X_{pt})}{\sigma_{pt}}$$

The requirements for the analytical performance are generally considered as fulfilled if

$$-2 \leq z \leq 2 .$$

#### 3.7.1 Warning and action signals

In accordance with the norm ISO 13528 it is recommended that a result that gives rise to a z-score above 3,0 or below -3,0, shall be considered to give an "action signal" [3]. Likewise, a z-score above 2,0 or below -2,0 shall be considered to give a "warning signal". A single "action signal", or "warning signal" in two successive PT-rounds, shall be taken as evidence that an anomaly has occurred which requires investigation. For example a fault isolation or a root cause analysis through the examination of transmission error or an error in the calculation, in the trueness and precision must be performed and if necessary appropriate corrective measures should be applied [3].

In the figures of z-scores DLA gives the limits of warning and action signals as yellow and red lines respectively. According to ISO 13528 the signals are valid only in case of a number of  $\geq 10$  results [3].

### 3.8 z'-Score

The z'-score can be used for the valuation of the results of the participants, in cases the standard uncertainty has to be considered (s. 3.8). The z'-score represents the relation of the deviation of the result ( $x$ ) of the participant from the respective consensus value ( $X$ ) to the square root of quadrat sum of the target standard deviation ( $\hat{\sigma}$ ) and the standard uncertainty ( $U_{x_{pt}}$ ) [3].

The calculation is performed by:

$$z'_i = \frac{x_i - x_{pt}}{\sqrt{\sigma_{pt}^2 + u_{(x_{pt})}^2}}$$

If carried out an evaluation of the results by means of z 'score, we have defined below the expression in the denominator as a target standard deviation  $\sigma_{pt}'$ .

The requirements for the analytical performance are generally considered as fulfilled if

$$-2 \leq z' \leq 2 .$$

For warning and action signals see 3.7.1.

### 3.9 Reproducibility coefficient of variation ( $CV_R$ )

The coefficient of variation ( $CV_R$ ) of the reproducibility (= relative reproducibility standard deviation) is calculated from the standard deviation and the mean as follows [4, 13]:

$$CV_R = \frac{S_R * 100}{X}$$

In contrast to the standard deviation as a measure of the absolute variability the  $CV_R$  gives the relative variability within a data region. While a low  $CV_R$ , e.g. <5-10% can be taken as evidence for a homogeneous set of results, a  $CV_R$  of more than 50% indicates a "strong inhomogeneity of statistical mass", so that the suitability for certain applications such as the assessment of exceeded maximum values or the performance evaluation of the participants possibly can not be done [3].

### 3.10 Quotient $S^*/\sigma_{pt}$

Following the HorRat-value the results of a proficiency-test (PT) can be considered convincing, if the quotient of robust standard deviation  $S^*$  and target standard deviation  $\sigma_{pt}$  does not exceed the value of 2. A value > 2 means an insufficient precision, i.e. the analytical method is too variable, or the variation between the test participants is higher than estimated. Thus the comparability of the results is not given [3].

### 3.11 Standard uncertainty

The consensus value has a standard uncertainty  $U(X_{pt})$  that depends on the analytical method, differences between the analytical methods used, the test material, the number of participant laboratories (P) and perhaps on other factors. The standard uncertainty of the assigned value ( $U(x_{pt})$ ) for this PT is calculated as follows [3]:

$$u_{(x_{pt})} = 1,25 \times \frac{s^*}{\sqrt{p}}$$

If  $U(x_{pt}) \leq 0,3 \sigma_{pt}$  the standard uncertainty of the consensus value needs not to be included in the interpretation of the results of the PT [3]. A clear exceeded the value of 0,3 is an indication that the target standard deviation was possibly set too low for the standard uncertainty of the assigned value.

The quotient  $u(x_{pt})/\sigma_{pt}$  is reported in the characteristics of the test.

#### 4. Results

##### Comments to the distribution of the results:

The kernel density plots showed for all elements except barium nearly a normal distribution of results (figures see documentation 5.3). Partly slight shoulders and separate smaller peaks can be seen, which are due to individual values and outliers.

In the case of barium, a distribution of results with two peaks can be seen. However, the information provided by the participants on the methods gave no obvious indications of such an array of results. Therefore, the statistical analysis of all results for barium was carried out together taking into account the standard uncertainty by z'-score.

##### Comments to the statistic data:

For Rb, Ti and Y there were < 7 results, therefore no statistical evaluation could be done.

The target standard deviation was calculated for all other elements according to the model of Horwitz.

For Al, Ba and I the distribution of results showed an increased variability. The quotients  $S^*/\sigma_{opt}$  were clearly above 2,0. Valuation of the three elements was done considering the standard uncertainty by z'-score. The quotients  $S^*/\sigma_{opt'}$  were in the range of 2,0 then (see table 4).

For the other elements the distribution of results showed a normal to low variability. The quotients  $S^*/\sigma_{opt}$  were all below 2,0, in part below 1,0 (see table 4).

The robust standard deviation as well as the repeatability and reproducibility standard deviations were in the range of established values for the applied methods (see 3.6.2).

The comparability of results is given.

The quotient  $U(x_{opt})/\sigma_{opt}$  was low for As, Cd, Co, Cu, Mn, Mo and Pb (< 0,3). For Cr, Fe, Ni, Li and Zn the quotients were (slightly) increased in the range of 0,33 to 0,42 and for Se and V 0,58 and 0,56.

67% to 100% of results were in the target range.

**Table 4:** Selected statistic data of the present PT  
(SD = standard deviation, CV = coefficient of variation)

## 5.2 Homogeneity

### 5.2.1 Homogeneity of bottled PT-samples

Homogeneity test of copper by ICP-OES (VDLUFA III, 10.8.2):

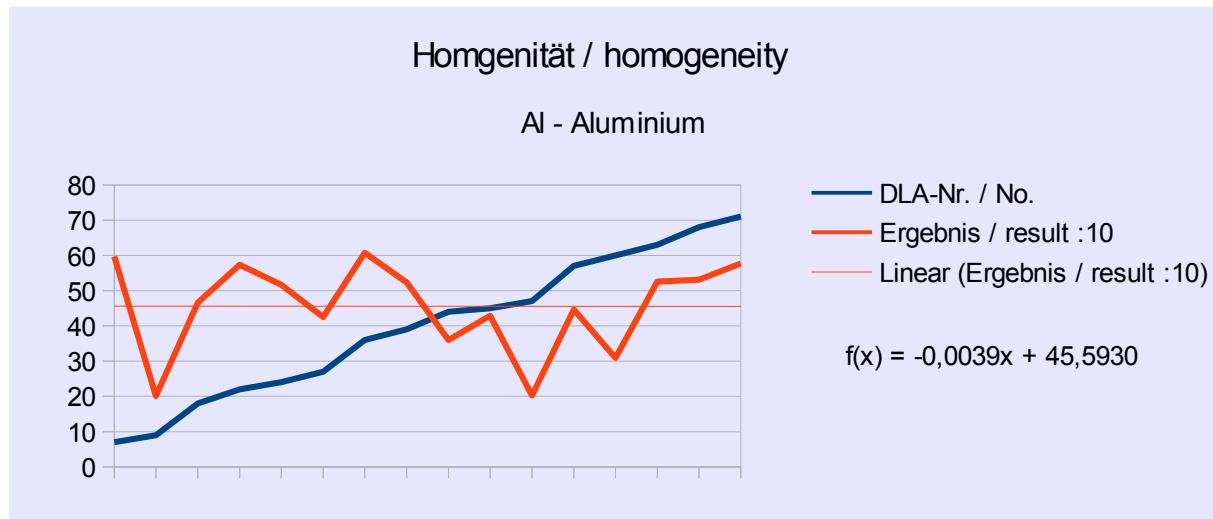

Independant samples	mg/kg
1	5,96
2	6,03
3	5,21
4	5,57
5	5,97

Mean 5,75  
Repeatability Standard Deviation 0,352 6,12%

### 5.2.2 Comparison of sample numbers / test results and trend line

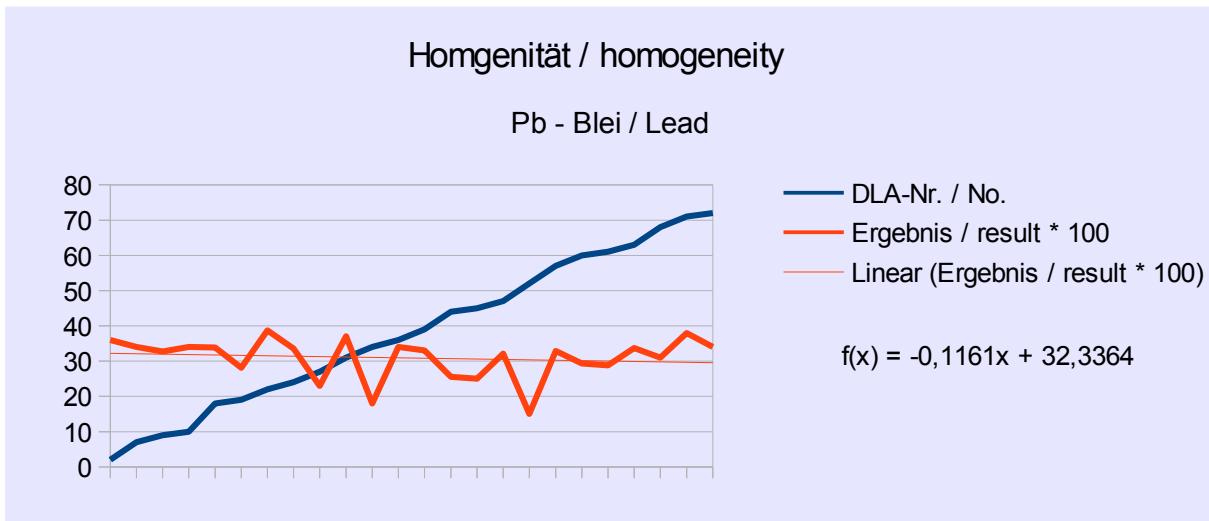

By comparison of the increasing sample numbers and the measurement results, the homogeneity of the chronological bottled PT item can be characterized with the help of the trend line function:

<b>A1 - Aluminium</b>	
Target standard deviation $\sigma_{pt}'$	65,9
Sample numbers	7 - 71
Total numbers of samples	16
Slope:	-0,0388
Trend line range	455,93 - 455,31 mg/kg
Deviation trend line	455,62 ± 0,310 mg/kg
Percent of $\sigma_{pt}'$	0,47 %

**Abb. 37:** Trendfunktion Probennummern / Al Ergebnisse (1/10 dargestellt)  
**Fig. 37:** trend line function sample number / Al results ( $\times 10$  shown)

<b>Pb - Lead</b>	
Target standard deviation $\sigma_{pt}$	0,0592
Sample numbers	2 - 72
Total numbers of samples	24
Slope:	-0,0012
Trend line range	0,3234 - 0,2956 mg/kg
Deviation trend line	0,3095 ± 0,0139 mg/kg
Percent of $\sigma_{pt}$	23,5 %

**Abb. 38:** Trendfunktion Probennummern / Pb Ergebnisse (\*100 dargestellt)  
**Fig. 38:** trend line function sample number / Pb results (\*100 shown)

### 5.3 Kernel Density Plots of Results

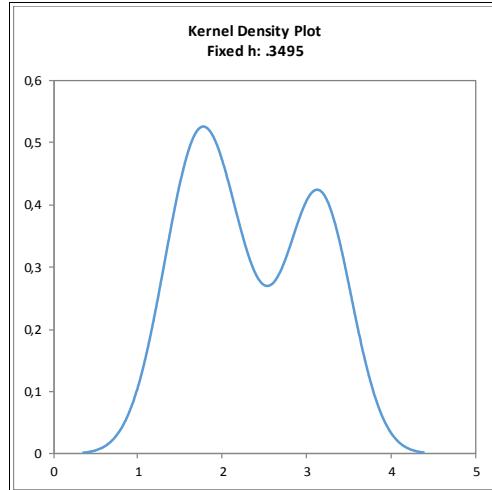

**Abbildungen:**

Kerndichte-Schätzungen  
der Teilnehmerergebnisse  
(mit  $h = 0,75 \times \sigma_{opt}$  von Xpt)

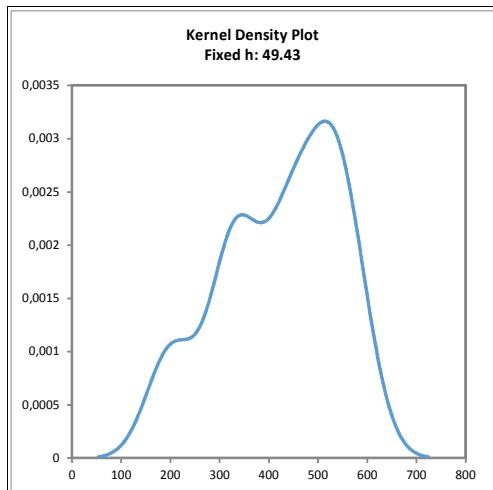

**Figures:**

Kernel density plots  
of participants' results  
(with  $h = 0,75 \times \sigma_{opt}$  of Xpt)

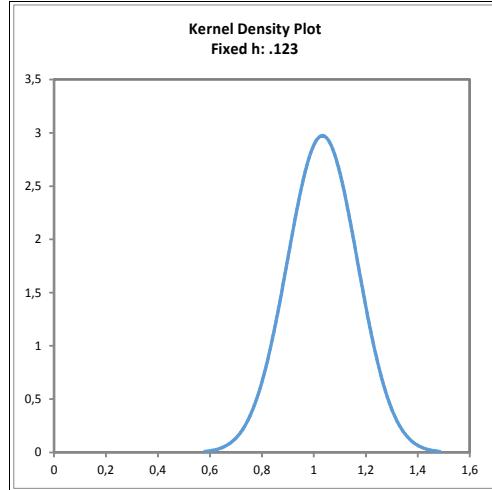

Ba – Barium

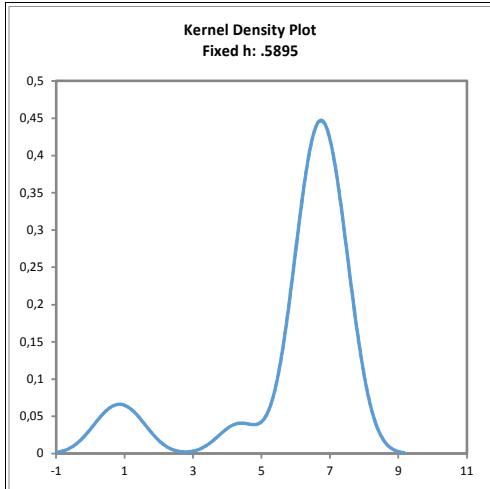

Al – Aluminium

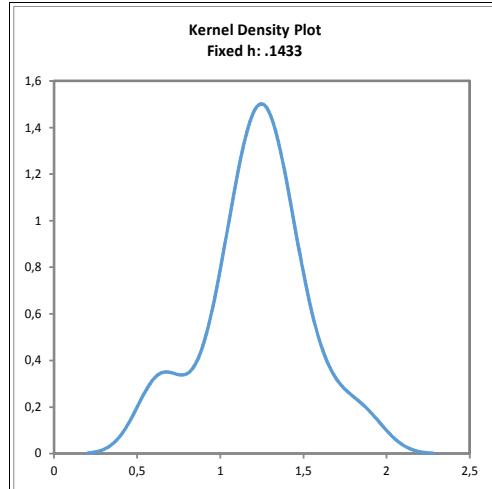

Cd – Cadmium

As – Arsen / Arsenic

Cr – Chrom / Chromium

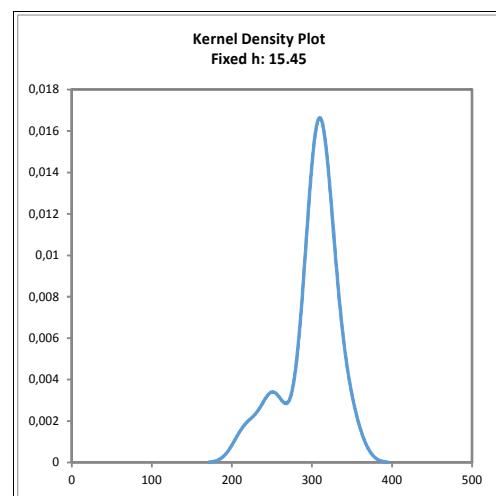

**Abbildungen:**

Kerndichte-Schätzungen  
der Teilnehmerergebnisse  
(mit  $h = 0,75 \times \sigma_{pt}$  von Xpt)

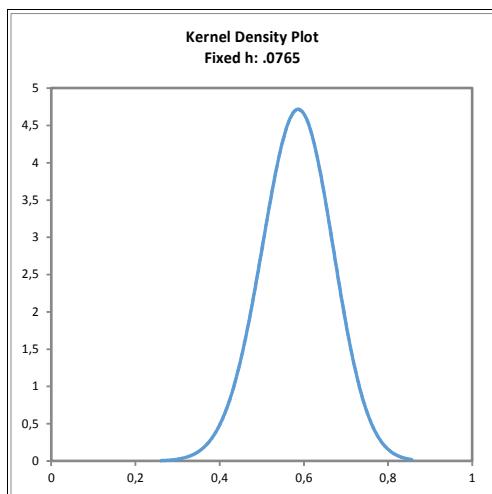

**Figures:**

Kernel density plots  
of participants' results  
(with  $h = 0,75 \times \sigma_{pt}$  of Xpt)

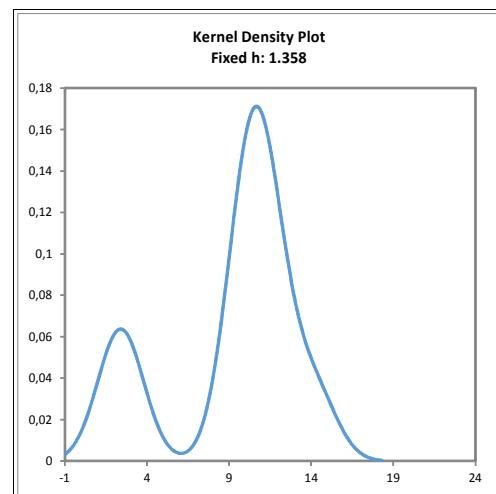

Fe - Eisen / Iron

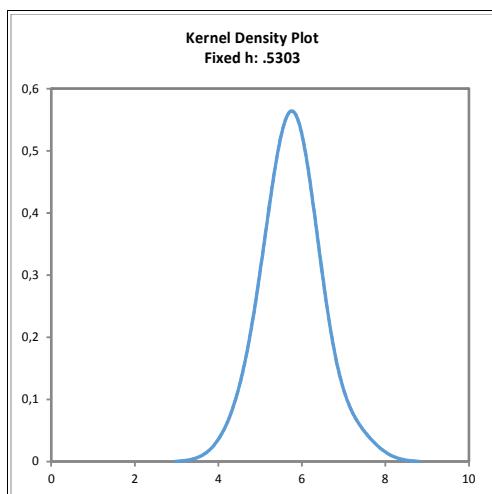

Co - Kobalt / Cobalt

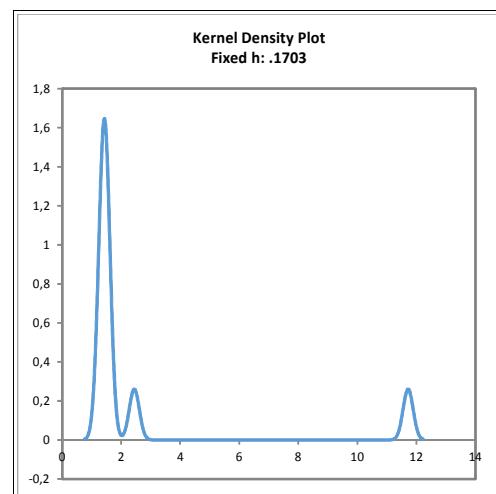

I - Iod / Iodine

Cu - Kupfer / Copper

Li - Lithium

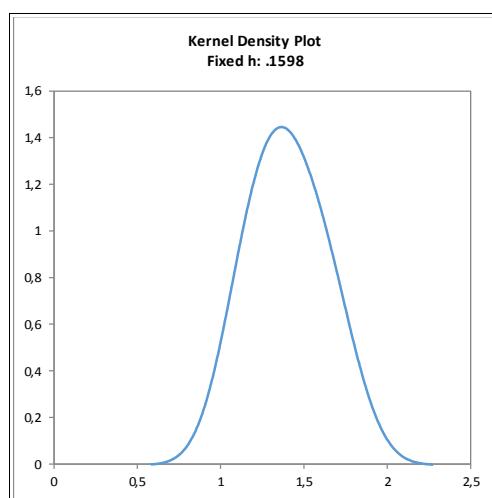

**Abbildungen:**
